**\*\*\*Processor Notes\*\*\***  
**ADSS 1996-1999**

1. Published statistics, including a few variables in this codebook, may not be exactly reproducible from the data in the public use file due to the disclosure protection procedures that were implemented.
2. The Data File User's Manuals provided in the codebooks contain references to SAS transport databases originally created by the data producers. To provide the data to users in a format that is neither system nor platform specific, the data files are in ASCII text format with SAS and SPSS data definition statements. Additionally, the number of variables found in the data files differ from the original number of variables cited by the data producers. The unweighted frequencies provided in the codebooks correspond to the data files.
3. In the Client Abstract data files, for the variable A62, "TEST RESULTS", the abstractor's instructions were to code "1 = Positive (leave blank if negative or not applicable)". Accordingly, negative test results were combined with inapplicable responses that are coded as -9. Any analysis of this series will be affected by this combining of negative and inapplicable responses.
4. In the Client Abstract data files, a new variable was created for A65 by the data producers: "TREATMENT EPISODES IN THE LAST 12 MONTHS". Therefore the questionnaire and variable information do not match. The new variable provides the number of treatment episodes in the prior 12 months, rather than a dichotomous response to whether or not the respondent had any treatment during this timeframe.
5. Disclosure analysis was performed on the ADSS files by SAMHDA, resulting in modifications to the data. These are explained in the following section, "Confidentiality Protection".
6. The Phase I facility public use file includes 2394 of the original 2395 records. One facility's record was deleted due to the presence of outlying data that could potentially identify the facility.
7. The Stratified Jackknife Factor files for Phase I and Phase II/III list values for the jackknife replication factors for use with the SUDAAN and WesVar statistical software only. These files are not intended for use with other statistical packages.
8. The Stratified Jackknife Factor files are space-delimited ASCII data files containing 1 record each. A detailed description of the use of these files is included in this codebook.
9. The jackknife factors are in the order expected by WesVar. The first factor corresponds to the first replicate, the second corresponds to the second replicate, and so on to the 200th factor, which corresponds to the 200th replicate.
10. The Phase I Finite Population Correction file contains the finite population correction factors (FPC) for use with the WesVar and SUDAAN statistical software only. The space-delimited ASCII data file contains 200 records and 1 variable. This file is not intended for use with other statistical packages.
11. The FPCs are in the order expected by WesVar. The first FPC corresponds to replicate 1, the second FPC to replicate 2, and so on to the 200th FPC, which corresponds to the 200<sup>th</sup> replicate.

## **Confidentiality Protection**

Disclosure analysis for the ADSS files was conducted by the Substance Abuse and Mental Health Data Archive (SAMHDA). Measures taken to protect the confidentiality of the ADSS facility and client records included (1) using microaggregation for problematic variables, (2) deleting direct identifier variables such as facility name, and (3) recoding variables. The disclosure protection procedures allow nearly all of the data to be publicly released, take into consideration the most likely analytic uses of the data, and ensure the confidentiality of both facilities and clients.

## **Microaggregation**

Microaggregation as applied to ADSS involved identifying problematic variables, sorting records by the first problematic variable, grouping records into three based on their value for this variable, averaging the values for each grouping, and applying the average to the records in each group. This was repeated for each of the problematic variables, which included the client count and financial data found in the Phase I Facility File. Cells with values of zero were excluded from microaggregation.

Microaggregation is a recoding method in which each variable has a set of ranges defined for it. For each variable, the range replaces each true record value. Such ranges (recodes) are usually defined summarily, irrespective of the data; in microaggregation the data themselves determine the ranges. The values most impacted by this approach are likely to be outliers or the values at either tail of a distribution. In other types of disclosure procedures, however, those values would be suppressed or top- or bottom-coded, which typically distorts the data substantially more than microaggregation (e.g., \$500,000; \$678,000; and \$1,750,000 would become “\$500,000 or more”). Microaggregation was preferable to these other methods because it allows statistics such as measures of central tendency to be run (e.g., to obtain average client counts and revenues), which are likely to be of interest to researchers. Researchers may want to categorize the ADSS data in performing their own analyses. Microaggregation allows them to do this in whatever way works best for them, without attempting to pre-determine the categories that would work for the most analysts.

The steps involved in the microaggregation were to:

1. Identify the problematic variables.
2. Microaggregate the variables identified, excluding values of zero.
3. Recalculate variables as necessary, based on the variables that were microaggregated.

Two Phase I variables were microaggregated: total substance abuse treatment revenue (D7) and total clients in all types of care on October 1, 1996 (B1J2). The total treatment revenue (D7) was carried forward to two additional variables (D8TOT and D12D). All of these “total revenue” variables provided the same data and respondents were instructed to copy the D7 total to D8TOT and D12D. All three of these variables were treated as microaggregated variables in determining the impact to the data.

The microaggregated variables were included in tables in the facility questionnaire that specified breakdowns of total revenue and client counts (the B1, B2 and D8 tables). Therefore, it was necessary to address the problem of having columns within the tables add correctly. Each cell within these tables represents a different variable. The totals were microaggregated and the number in each cell was recalculated by applying the relative percentage of the total for each cell. Totals were microaggregated, rather than sub-parts of the tables because all records had totals but not all records had valid numbers in the other cells in the tables. The more records that are microaggregated, the more closely the records are likely to cluster and the less impact there is to the data. These tables included 191 variables.

The only change to the Phase II Administrator file was the carrying over of the total substance abuse treatment revenue value from Phase I. This is Q52 in the Phase II file. No changes were made to the client files, other than the deletion of administrative variables and variables such as date of birth.

The ADSS Cost Study included a computerized desk audit to check for consistency and accuracy of data previously collected in the Phase I Facility and Phase II Administrator files. Three post-audit Cost Study variables were microaggregated: NB12, ND7, and NQ52. Related variables were recalculated based on the microaggregated data.

## **Results of Microaggregation**

In order to assess the impact to the data, for the microaggregated and recalculated variables, the cells that changed more than five percent in either direction were calculated as a percentage of valid cells (including zero) and as a percentage of total cells. Because a large number of valid values in the data are zero, we also calculated the cells that changed more than five percent as a percentage of non-missing and non-zero cells. We included all three revenue variables as microaggregated, though the original values for all three variables were the same. The results are provided in Table 1 and show that less than one percent of the non-missing and non-zero microaggregated variables changed more than five percent, while 3.6 percent of the recalculated variables changed more than five percent. Of all valid cells (including zero) for microaggregated variables, less than one percent changed more than five percent while fewer than two percent of the recalculated variables did so.

For the ADSS Cost Study, means by facility type were compared pre- and post-microaggregation. Change in means by facility type ranged from -2.9 percent to +2.1 percent. Overall changes in means were negligible, which is the intended result of micro-aggregation.

**Table 1. Overall effects of microaggregation and recalculation.**

PHASE I FACILITY FILE		
	Microaggregated	Recalculated
Number of Variables	4	191
Record Count	2,394	2,394
Cells w/valid data (non-missing, non-0)	9,546	92,544
Cells w/missing data	0	289,062
Cells w/ data value=0	30	75,648
Total cells	9576	457,254
Change of > +/- 5%	82	3,304
Percentage (non-missing/non-0 cells)	0.859%	3.570%
<b>Percentage (valid cells, including 0)</b>	<b>0.856%</b>	<b>1.964%</b>
Percentage (total cells)	0.856%	0.723%

We further examined the impact to the data by comparing pre- and post-microaggregation ratios and means and by running a regression model on the pre- and post-microaggregated data to determine if significance results were comparable between the files.

*Means* were obtained by type of care and facility ownership for the microaggregated variables. The percent change in the means of these variables by both type of care and facility ownership ranged from zero to .9 percent, as shown in Tables 2 and 3. For the three total revenue variables that were impacted by microaggregation, the results are exactly the same for each variable. Therefore, only the result for one of these variables (D7) result is reported.

**Table 2. Pre- and Post-Microaggregation Means By Type of Care.**

PHASE I FACILITY FILE

6 Tribal Government	D7 Total subs abuse trt revenue	11	11	809306.2	813274.0	3967.8	0.5%
	B1j2 Total clients all care 10/1	11	11	68.2	67.9	-0.3	-0.4%

The *regression* model used the revenue variable “Other government funds” (D8G) as the dependent variable. This is a limited dependent variable in that roughly 86 percent of the 2394 programs in the sample database have an actual or implied zero (0) value for the amount of government funding. Therefore, an ordinary linear regression analysis of the full data is not appropriate and four regression analyses were tested. All analyses were done in STATA and incorporate the global sample weight variable (PH1FW0); however, the analysis did not include design effects for stratification. The data set was prepared with replicate weights for Balanced Repeated Replication analysis of complex sample design standard errors. This would require the use of Wesvar PC 4.0, which does not permit estimation of one of the models evaluated. Estimated coefficients computed in weighted analysis using STATA will exactly match those from the full analysis based on the complex sample design; however, the standard errors of the coefficients (shown in Table 6) are likely to be slight underestimates of the standard errors that would be obtained in an analysis that also included the stratification and weighting effects for the sampling of programs.

Model 1: Ordinary least squares regression on only the cases that have a nonzero amount for the government revenue variable. There are n=322 cases in this analysis.

Model 2: Ordinary least squares regression on only the cases that have a nonzero amount for the government revenue variable. The dependent variable is the natural log of the original non-zero government revenue amount. There are n=322 cases in this analysis.

Model 3: A Logistic regression model to analyze the probability that a program receives government revenue for its services. There are n=2394 cases in this analysis.

Model 4: A Tobit regression model for the left-censored (zero) dependent variable. There are n=2394 cases in this analysis.

Table 4 presents the results comparing the fit of each of these four models to the data before and after the microaggregation disclosure protection, showing that the regression model coefficients and the interpretation of the significance of the associated effects are quite robust against the microaggregation “blurring” of the data.

## **Deletions**

Any variables that could specifically identify a facility were removed from the file. These included variables such as facility name and address, facility director's name, name and address of parent organization, and National Master Facility Index (NMFI) identifiers. Also deleted were administrative variables such as interviewer initials and date and time of the interview and the "other, specify" variables that were provided as verbatim responses and had not been numerically coded. Client date of birth was also removed. One record was deleted from the Phase 1 facility file because it was either an extreme outlier or the revenue data had been coded or entered incorrectly.

## **Recodes**

In addition to the variables that were recoded due to the microaggregation procedures, some variables were recoded to make them more analytically useful. For example, time intervals such as length of time for treatment, were recoded to a standard unit (e.g., a variable with responses of days, weeks, or months was recalculated to days). This was not possible for all time units because some variables had response options that could not be reduced to a standard unit such as *sessions*, days, weeks, etc. Also, records were randomized and facility and client identification numbers were removed and replaced with sequential IDs, retaining the linkages between the files.

The codes for substance abuse and mental health disorders based on the Diagnostic and Statistical Manual of Mental Disorders (DSM) criteria were recoded from the raw DSM codes into groups that made this variable more analytically useful. Table 7 shows the recoded diagnostic categories.

**Table 7. Diagnosis recodes**

<u>ORIGINAL CODES</u>	<u>RECODES</u>
0.00	0 No Diagnosis
291.00-291.99	1 Alcohol-induced Disorder

## 1. INTRODUCTION

This manual documents the Alcohol and Drug Services Study (ADSS) Phase III data files and provides guidance on using the file to produce national estimates. The manual includes a codebook of the Phase III data variables with a frequency distribution for each variable. The ADSS was sponsored by the Substance Abuse and Mental Health Services Administration (SAMHSA) and was conducted by the Schneider Institute for Health Policy at Brandeis University in Waltham, Massachusetts and by Westat in Rockville, Maryland.

The ADSS is a national survey of substance abuse treatment facilities and clients. The objective of ADSS was to collect detailed information on the characteristics of substance abuse treatment facilities and on clients discharged from those facilities. The data will be used to develop better estimates of client length of stay and the costs of treatment and to describe the post-treatment status of clients. ADSS is the continuation of the 1990 DSRS and 1995 SROS surveys and provides more detailed information on the organization of the national treatment system and the clients in treatment. ADSS consists of three phases: (1) a facility-based telephone interview with a representative sample of about 2,400 substance abuse treatment facilities; (2) a record-based survey of clients where client-level information was collected on a sample of over 5,000 clients discharged during a 6-month period and more than 900 in-treatment methadone clients; and (3) followup personal interviews with the sample of clients and a comparison group to determine post-treatment status in terms of substance use, economic status, criminal justice status, and further substance abuse treatment episodes. Urine testing was conducted to validate self-report of drug use.

Phase I involved a telephone interview to collect data from a national sample of 2,395 substance abuse treatment facilities selected from SAMHSA's National Master Facility Inventory of known facilities. Phase I facility interviews were conducted from December 1996 through June 1997. The questionnaire included point-prevalence data from October 1, 1996 and annual data for the most recent 12-month period for which data were available. The questionnaire was mailed to the facilities about 2 weeks before they were contacted by telephone to collect the information, allowing the facility staff the time necessary to obtain answers to the questions before being asked to provide the answers over the telephone. See the **ADSS Methodology Report**<sup>1</sup> for the survey methodology for Phase I.

Phase II, which involved site visits to a sample of 280 of the facilities that participated in Phase I, was conducted from August 1997 through April 1999. The visit included an in-person interview with the

---

<sup>1</sup> Alcohol and Drug Services Study (ADSS) Methodology Report. (2000). U.S. DHHS Substance Abuse and Mental Health Services Administration (SAMHSA).

facility director or administrator, compilation of a sampling frame and selection of a sample of client records, and collection of client-level data from the sample of client records at each facility. In total, client-level data were collected for 6,720 clients. These included 5,005 clients discharged from treatment between February 1997 and December 1998 and 925 in-treatment methadone clients enrolled at the facility on the day of the administrator interview. The remaining 790 abstracts were for an early drop-out comparison group. See the **ADSS Methodology Report** for more detailed survey methodology for Phase II.

Phase III involved followup interviews with selected Phase II clients who could be located between February 1998 and May 1999. Urine samples were collected immediately following each interview. See Chapter 2 for more detail on the Phase III methodology.

## 2. OVERVIEW OF THE ADSS PHASE III FOLLOWUP SURVEY METHODOLOGY

Phase III of ADSS consisted of followup interviews and urine sample collection from substance abuse treatment clients whose treatment records were sampled and abstracted during Phase II. Client history and treatment information, along with post-treatment status in terms of drug and alcohol use, criminal behavior, return to treatment, and other factors of social functioning were obtained in the interview.

The original client sample selection was made during ADSS Phase II at a nationally representative sample of 280 residential and outpatient (methadone and nonmethadone) treatment facilities subsampled from the 2,395 sample treatment facilities participating in the ADSS Phase I facility survey. See the **ADSS Methodology Report** for more detailed information on the sampling of facilities and clients in the earlier phases of ADSS.

The Phase III followup interviews were conducted from February 1998 through May 1999, completing followup interviews with clients approximately 1 year after their Phase II sampled treatment episode. There was considerable variation in the length of the followup period, especially for hard-to-locate clients.

Clients in the Phase III followup study are nationally representative of clients discharged from substance abuse treatment during a 6-month period, with the following facility and client type exclusions:

- Facility exclusions - Facilities with hospital inpatient-only type of care, facilities treating alcohol-only clients exclusively, half-way houses without paid treatment staff, solo practitioners, correctional facilities, Department of Defense facilities, Indian Health Service facilities, and facilities that were intake and referral only were excluded from Phase II of ADSS.
- Client exclusions - Clients who were under 18 years of age, although included in the Phase II abstract study, were excluded from the client followup in Phase III. Methadone clients in the discharge sample, included in the Phase II abstract study, were also excluded from the Phase III followup. (However, as an additional representation of methadone clients, a separate cross-section of "in-treatment" methadone clients (ITMCs) was sampled in the Phase II abstract study and this cross-section ITMC group was included in the Phase III client followup.)

The Phase III followup study included four groups of clients, corresponding to the following four Phase III substudies - Main Study, Incentive Study,<sup>2</sup> In-Treatment Methadone Client Study (ITMC), and an Early Dropout Comparison Study:

**Main Study** - A probability sample of nonhospital residential and outpatient nonmethadone discharges during a 6-month period at each Phase II sample facility. National estimates of the followup data for this 6-month discharge cohort<sup>3</sup> can be calculated using the Phase III sample weights on the file (see Chapter 4 for use of the sample weights.)

The lower than expected followup response rates encountered in Phase III may increase the bias in all estimates derived from the data. Although Phase III sample weights are adjusted for client nonresponse, such an effort can only help to lessen the effects of non-response, not eliminate them completely. See Chapter 3 of the ADSS Methodology Report for a discussion of the impact of the response rates and the measures taken to reduce bias in the estimates.

The Main Study clients were offered \$15 to complete the followup interview and \$10 to provide a urine specimen. (The outpatient non-methadone group also serves as the \$15/\$10 payment group in the Incentive Study.)

**Incentive Study** - A probability sample of outpatient nonmethadone discharged clients sampled in four incentive payment groups (the file includes raw data only, no sample weights):

- \$0/\$0 - Clients receiving no payment for the interview or the urine specimen;
- \$0/\$10 - Clients receiving no payment for the interview, \$ 10 for the urine specimen;
- \$15/\$10 - Clients receiving \$15 for the interview and \$10 for the urine specimen  
(these are the Main Study outpatient nonmethadone clients, repeated in the  
Incentive Study data set without weights);
- \$25/\$10 - Clients receiving \$25 for the interview and \$10 for the urine specimen.

The Phase III Incentive Study file is left unweighted since the response rates varied by incentive group, making combined analysis and calculation of national estimates inappropriate (the Phase III Main Study data should be used for national estimates.) The appropriate use for the Phase III Incentive Study data

---

<sup>2</sup> The Main Study client sample and the Incentive Study client sample were a single combined outpatient sample in the Phase II abstract study. Only at the introduction of the four different incentive payment levels in the Phase III followup study are the outpatient clients split into the Main Study versus the Incentive Study data files.

<sup>3</sup> Since the Main Study sample represents a cohort of clients discharged during a 6-month period, conversion of any estimated counts for this 6-month cohort to estimated counts for a 12-month cohort can be made by multiplying the weighted estimates for this group by 2.

is the comparison of the raw data for analyzing response bias and sample bias related to the different incentive payments.

**In-Treatment Methadone Client (ITMC) Study** - A probability sample of methadone clients "in treatment" on the day of the Phase II facility site visit. National estimates of the followup data for this in-treatment cohort of methadone clients can be calculated using the Phase III sample weights on the file (see Chapter 4 for use of the sample weights.)

**Early Dropout (EDO) Comparison Study** - A nonprobability convenience sample of outpatient nonmethadone clients who left treatment after a single day or visit. The comparison group was selected from cooperating facilities, to serve as a proxy for untreated substance abusers (the file includes raw data only, no sample weights.)

## 2.1 Sampling

The clients followed up in Phase III were sampled in Phase II. Phase II sampling consisted of three stages. First, the country was partitioned into approximately 400 geographic primary sampling units (PSUs) and a representative sample of 62 were selected on the basis of demographic and economic characteristics. Within these 62 PSUs, a stratified subsample of 306 Phase I responding facilities was selected using a probability proportional to size (PPS) design. The last stage in Phase II consisted of random samples of discharges or methadone in-treatment clients being chosen from within the selected facilities. The Phase III sample consisted of clients whose records were abstracted in Phase II and who were 18 years or older at the time of the interview. Clients who were methadone discharges were excluded from Phase III. For more details on the Phase II and III sampling and weighting processes, refer to the **ADSS Methodology Report**.

## 2.2 Survey Instrument

The Phase III client followup questionnaire contains three major sections: the first focuses on the period before the treatment episode; the second focuses on the treatment period reflected in the Phase II abstract; and the third focuses on the post-treatment period. The design of the questionnaire is discussed in the **ADSS Methodology Report**. A copy of the questionnaire can be found in Appendix A.

## 2.3 Data Preparation

Phase III survey data were recorded on paper forms by the interviewers. The completed forms were double key entered and verified. A detailed series of automated range and logic checks were performed to ensure that the data were internally consistent. Questionable values were checked against the hard-copy documents and corrected if possible.

## 2.4 Weighting

Phase III client weights were constructed for the Phase III Main Study interview file and for the Phase III In-Treatment Methadone Client file. The Phase III Incentive Study file and the Phase III outpatient nonmethadone early dropouts file are not weighted.

The major weighting steps were:

- Establishing client base weights,
- Raking, and
- Trimming.

### 2.4.1 Base Weights

The client base weights for the Phase III Main Study clients are the product of the Phase II abstract final weight and a weighting factor accounting for the split of the Phase II sample into the main and incentive studies. The In-Treatment Methadone Client Study (ITMC) base weights are equal to their associated final abstract weights, since no additional sampling was performed for this group in Phase III.

### 2.4.2 Raking

Raking was used to reduce variability in estimates using the final weights and to reduce nonresponse bias in the estimates. In raking, sampling weights are adjusted so that the weighted totals within cells are equal to control totals based on a more reliable source. The assumption is that forcing weighted totals to equal more reliable values at the cell level will reduce variability and bias of other estimates which

correlate with any of the factors used to define cells. Raking addresses nonresponse and removes the need for any other form of nonresponse adjustment.

Facility-level characteristics, abstract-level characteristics, whether tracing was required to locate the client, and various interview and urine testing outcome variables were used to define the raking cells. See the **ADSS Methodology Report** for details.

### 2.4.3 Trimming

Weight trimming is the pragmatic operation of reducing the disproportionately high weights of a few overly influential respondents and redistributing it among lower weighted respondents. In moderation, trimming is an acceptable protection against a small set of respondents having too much impact on estimates in a study, but trimming does introduce bias into an analysis and should be held to a minimum.

In Phase III of ADSS, the trimming of clients weights was performed using separate techniques for the Main Study and for the ITMC study. For the Main Study, outlier weights were trimmed within weighting groups as defined by the variable TXCARE (client type of care). TXCARE is a derived variable based on entries in the Phase II client abstract which has two values for Phase III respondents: residential (R) and outpatient nonmethadone (N). For the ITMC clients, trimming did not use TXCARE. For these respondents, outlying weights were identified through stem and leaf plots. No one arbitrary or analytical trimming rule was used. The objective was to trim as little as possible while identifying outlier weights in order to protect against a small number of clients dominating estimates due to the size of their weights. See the **ADSS Methodology Report** for details.

### 2.4.4 Final Client Weights

The final full-sample client weight for each client is a product of the client base weight, the client's raking factor, and the client's trimming factor. The variable containing the final full-sample client weight for the Main Study is named C3FWM0. The corresponding final weight for the ITMC study is named C3FWT0. These weights can be used to estimate means, totals, proportion of client characteristics, and so forth.

#### **2.4.5 Variance Estimation**

Replicate weights were created for clients using the stratified jackknife method. The client replicate weights were obtained by using the abstract replicate weights for Phase II and applying the same procedures that were implemented for the full-sample client weighting. That is, the replicate weighting procedures for the clients included replicating the base weights, adjusting the replicate base weights for unknown eligibility status, adjusting the replicate weights for incomplete abstracts, and lastly trimming the replicate weights. By repeating the various weight adjustment procedures in each set of replicate weights, the impact of these procedures is appropriately reflected in the sampling variance of the estimator. Chapter 4 describes how to use the replicate weights to compute appropriate variance estimates.

### 3. ADSS PHASE III FOLLOWUP SURVEY DATA FILES

The following data files contain the ADSS Phase III Client Followup Questionnaire and urinalysis data and supplementary data useful in constructing national estimates from the questionnaire data:

- P3QUEX.XPT: SAS transport data set containing the 4 Phase III Client Followup Files:
  - P3QUEXM: Phase III Discharge Client Followup (Main Study) (1,184 records)
  - P3QUEXI: Phase III In-Treatment Methadone Client Followup (618 records)
  - P3QUEXE1: Phase III Early Dropout Comparison Study Discharge Client Followup (345 records)
  - P3QUEXN: Phase III Incentive Study Client Followup (Incentive Study) (1,339 records)

The following files contain the responses to the open-ended questions in the followup questionnaire. Since there are multiple responses from some respondents, there are more records than respondents in these files.

- P3TEXT.XPT: SAS transport data set containing the responses to the three open-ended questions in the Phase III Client Followup Questionnaire.
  - P3TEXTM: Phase III Discharge Client Followup Open-ended Questions (Main Study) (3,938 records)
  - P3TEXTI: Phase III In-Treatment Methadone Client Followup Open-ended Questions (1,968 records)
  - P3TEXTE1: Phase III Early Dropout Comparison Study Client Followup Open-ended Questions (1,107 records)
  - P3TEXTN: Phase III Incentive Study Client Followup Open-ended Questions (Incentive Study) (4,496 records)
- JKN\_FAC2.DAT: Stratified jackknife factors (JKN) (1 record, 78 values). It is formatted for use with the WesVar Complex Samples program. Note that these are the same jackknife factors as are used for Phase II.

Each of these files is described briefly below.

### 3.1 Phase III Client Followup Files

The Phase III Client Followup Files are contained in a SAS transport dataset named P3QUEX.XPT. The internal SAS file names, number of records, and number of variables for the four files contained in the transport dataset are summarized in Table 3-1.

Table 3-1. Phase III followup file names, descriptions, record counts, and variable counts

SAS file name	Description	Number of Records	Number of Variables
P3QUEXM	Discharge Client Followup Questionnaires (Main Study)	1,184	1,097
P3QUEXI	In-Treatment Methadone Client (ITMC) Followup Questionnaires	618	1,097
P3QUEXE1	Early Dropout Comparison Study Client Followup Questionnaires	345	991
P3QUEXN	Incentive Study Client Followup Questionnaires	1,339	991

These files represent the data collected on the Phase III Client Followup Questionnaire and the data from the urinalyses conducted on the consenting respondents. A copy of the followup questionnaire is included as Appendix A. The responses to three open-ended questions are recorded in a separate set of files because there can be multiple responses per client to each question.

The Discharge Client Followup File and the In-Treatment Methadone Client Followup File have more variables because they are weighted while the Incentive Study File and the Early Dropout Comparison Study Files are not weighted. Other than that, the layout of the four files is identical. In general, the order of the variables at the beginning of each file is the same as the order of the corresponding items in the followup questionnaire followed by a small number of derived variables based on responses to the questionnaire (e.g., F\_AGEINT, the client's age on the day of the interview). The questionnaire-related variables are followed by the results of the laboratory test on the urine samples and some urinalysis-related derived variables (e.g., U\_ANYDRG, which indicates whether or not the client was positive for any drug other than alcohol). These are followed by a number of variables copied from the Phase II abstract file for the convenience of the analyst (e.g., A73, the abstract record reason for discharge).

The weights and weighting variables come at the end of the two weighted files. For the main discharge study, the variable C3FWM0 is the client final full sample weight. It should be used for the purposes of making estimates at the national level. There are 78 client replicate weights (C3FWM1 - C3FWM 78). For the In-Treatment Methadone Study, the variable C3FWT0 is the client final full sample weight. It

should be used for the purposes of making estimates at the national level. There are also 78 client replicate weights on this file. They are named C3FWT1 through C3FWT78.

The four files are sorted by CLIENTID, the client identifier. Since the first part of CLIENTID is also the facility identifier, the files are also sorted by FACID, the facility identifier. CLIENTID can be used to link records to the Phase II client abstract data files. FACID can be used to link records to both the Phase I and the Phase II facility data files.

**3.2 Phase III Client Followup Open-ended Question Files**

The Phase III Client Followup Open-ended Question Files are contained in a SAS transport dataset named P3TEXT.XPT. The internal SAS file names, number of records, and number of variables for the four files contained in the transport dataset are summarized in Table 3-2.

Table 3-2. Phase III followup open-ended question file names, descriptions, record counts, and variable counts.

SAS file name	Description	Number of Records	Number of Variables
P3TEXTM	Discharge Client Followup Questionnaire Open-ended Questions (Main Study)	3,938	5
P3TEXTI	In-Treatment Methadone Client (ITMC) Followup Questionnaire Open-ended Questions	1,968	5
P3TEXTE1	Early Dropout Comparison Study Client Followup Questionnaire Open-ended Questions	1,107	5
P3TEXTN	Incentive Study Client Followup Questionnaire Open-ended Questions	4,496	5

These files represent the data collected in response to the Phase III Client Followup Questionnaire open-ended questions. A copy of the followup questionnaire is included as Appendix A. The open-ended questions are D84e, D84f, and D84g. They are introduced with the lead-in statement, “Now I would like to ask you a few questions on what you think about the treatment for alcohol or drug abuse you (received/are receiving).” The three open-ended questions are:

- What services (were/have been) most helpful?
- What services do you feel you could (have benefited/benefit) from which you (did not/have not) receive(d)?
- How do you think treatment could be improved?

Since these responses were of indeterminate length, multiple records were allowed for each respondent for each question. The responses are numbered sequentially for each question. Responses to question D84e are numbered 1301, 1302, 1303, etc. Responses to question D84f are number 1401, 1402, 1403, etc. Responses to question D84g are numbered 1501, 1502, 1503, etc. All files are sorted by CLIENTID, the client identifier, and RECNO, the record number within client. Since the first part of CLIENTID is also the facility identifier, the files are also sorted by FACID, the facility identifier. CLIENTID can be used to link records to the Phase II and III data files. FACID can be used to link records to the Phase I and II data files.

### **3.3 Phase III Stratified Jackknife Factor (JKN)**

The Phase III Stratified Jackknife Factor file is a space-delimited ASCII file containing one record. The file is name JKN\_FAC2.DAT. It lists values for the jackknife replication factors required for use of the jackknife procedure in WesVar. See Chapter 4, for a detailed description of the use of this file.

The jackknife factors are in the order expected by WesVar. The first factor corresponds to the first replicate, the second corresponds to the second replicate, and so on to the 78th factor, which corresponds to the 78th replicate.

#### **4. CALCULATING WEIGHTED ESTIMATES AND ACCOUNTING FOR THE ADSS PHASE III SAMPLE DESIGN IN VARIANCE ESTIMATION**

The sample design for the Alcohol and Drug Services Study (ADSS) consisted of a multi-stage stratified design. The first stage (Phase I) was a stratified probability proportionate to size (PPS) sample of facilities. Phase II consisted of multiple stages of sampling, which included the selection of a subset of Phase I responding facilities within 62 sampled primary sampling units (PSUs) and also involved the selection of client records for abstracting. Phase III consisted of followup interviews with eligible clients selected in Phase II, therefore, there was no further sampling of clients in Phase III. To discuss appropriate variance estimation procedures for estimates from Phase III data, a discussion of the Phase II sample design is necessary.

The multi-stage sample design for ADSS Phase II was complex and involved clustering, stratification, unequal probabilities of selection, and systematic sampling. Before the Phase II sample selection of facilities, the Phase I responding facilities were restratified based on their responses to the Phase I questionnaire. Next, the responding facilities were subset to 62 randomly selected PSUs, comprising counties or groups of counties. Subsequently, the Phase II sample of 306 facilities was selected using a stratified PPS design. In Phase II, once the facilities were selected and the facility administrators interviewed, client records were listed, sampled, and abstracted. Within all Phase II interviewed facilities, a sample of client discharge records from the most recent 6-month period was randomly selected and the data were recorded on a Phase II client record abstract form. For predominantly methadone treatment facilities, an additional sample of in-treatment client records was also randomly selected for the In-Treatment Methadone Client Study (ITMC). In Phase III, all Phase II clients for whom abstracts were completed were selected for followup interviewing with the exception of those who were under 18 years of age at the time of the interview and those who were methadone discharges.

The primary objective of this chapter is to provide the reader with enough information to facilitate basic data analyses that account for the ADSS complex sample design and to use the sample weights appropriately. Because variance computation needs to incorporate the ADSS complex design in its calculations, standard software routines in SAS and SPSS should not be used for computing variances for ADSS. Other software is recommended in this section. Two examples are provided to help explain how to do basic analyses using ADSS Phase III data: one for calculating estimates of population totals and one for performing a regression. The examples provide the instructions needed for simple analyses for any Phase III file, excluding the data files of early dropout clients and the incentive study file, for which no weights were created.

Replicate weights for ADSS Phase III were designed to capture the features of the ADSS sample design (e.g., effects from clustering, stratification, some effect from implicit stratification resulting from systematic sampling from a sorted list, and effects of PPS sampling),<sup>4</sup> as well as capturing the weighting effects on variance (e.g., trimming and raking). A discussion is provided below on how to approximate the number of degrees of freedom associated with variance estimates. Attention should be given to degrees of freedom when analyzing subgroups in ADSS data.

WesVar<sup>5</sup> is the recommended choice for calculating variance estimates in the ADSS data since the sample and replication scheme were designed with WesVar in mind. In this case, it is the recommended method for incorporating the effects of the ADSS sample design and weighting process of Phase III.

Software packages other than WesVar that will provide reasonable estimates of sampling error under the ADSS complex survey design are discussed later in this document. The two software packages discussed are SUDAAN<sup>6</sup> (Software for the Statistical Analysis of Correlated Data) and Stata.<sup>7</sup>

WesVar can calculate estimates of statistics such as means and proportions, along with their variance estimates. Furthermore, variance estimates can be computed for complex functions of estimates, including ratios, differences of ratios, and log-odds ratios. WesVar calculates standard errors, variances, and confidence intervals for the specified survey estimates and chi-square tests of independence for two-way tables of weighted frequencies. It also computes estimated coefficients for linear and logistic regression models and performs significance testing of a subset of linear combinations of variables. For further documentation on using WesVar, please refer to the WesVar Complex Samples User's Guide.

## 4.1 Background

Many types of statistics can be estimated in WesVar. This section describes how to estimate totals, ratios/proportions, and regression parameters. Creating estimates and their standard errors is largely controlled in WesVar by specifying table requests. A table request operates by calculating weighted totals for the specified variables of interest. Additional variables can be created by manipulating these totals.

---

<sup>4</sup> Replicate weights were formed under the stratified jackknife procedure (JKN).

<sup>5</sup> For more information on obtaining WesVar, contact the WesVar information line at (301) 517-2006 or send e-mail to wesvar@westat.com.

<sup>6</sup> For more information on SUDAAN, call 919-541-6602, fax 919-541-7431, or e-mail sudaan@rti.org

<sup>7</sup> For more information on Stata, call 800-782-8272, fax 979-696-4601, or e-mail stata@stata.com

#### 4.1.1 Calculating Weighted Totals

If there are  $n$  records in the file and the variable of interest is represented by  $y$ , the population total for  $y$  is estimated by the formula

$$\hat{Y} = \sum_{i=1}^n w_i y_i \quad (1)$$

where  $w_i$  is the full sample weight and  $y_i$  is the observed value of  $y$  for the  $i$ -th unit in the sample.

Totals can be estimated for domains by specifying variables from the source variables to define the table margins (on the tables panel).

#### 4.1.2 Calculating Ratio Means and Proportions

With weighted data, the estimate of a population mean is usually found by estimating the population total and then dividing by the sum of the weights. If the mean of  $y$  in the population is represented by  $\bar{Y}$ , then the formula for the ratio estimate of this quantity is

$$\hat{\bar{Y}} = \frac{\sum_{i=1}^n w_i y_i}{\sum_{i=1}^n w_i} \quad (2)$$

If  $y_i$  is a variable with  $y_i = 1$  or  $y_i = 0$ , then the resulting quantity is an estimate of a population proportion.

In a general ratio estimate, the denominator is the weighted total for some other variable, say  $x$ . For example, let  $y$  be the number of clients in a facility and let  $x$  be the number of full-time staff in the same facility. The population ratio of the total number of clients to the total number of full time staff,

$$R = \frac{Y}{X}$$

can be estimated by

$$\hat{R} = \frac{\sum_{i=1}^n w_i y_i}{\sum_{i=1}^n w_i x_i} \quad (3)$$

This is accomplished in WesVar using a computed statistic defined as  $RHAT=Y/X$ . The standard error of  $RHAT$ , a function of estimated ratios, is then computed. Domain analyses can also be performed for this variable by specifying table variables.

### 4.1.3 Regression

Regression facilitates fitting both linear and logistic regression models to data from surveys employing complex sample designs. A Regression Request is used to define a particular regression model, to estimate the model parameters, to test the fit of the overall model, and to test the significance of linear combinations of the independent variables in the model. Linear or logistic models can be specified on the Options panel by clicking on **Options** in the workbook tree, and selecting the dependent and independent variables of the specific model on the Models panel.

The general linear model is as follows:

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\varepsilon}$$

where  $\mathbf{Y}$  is the vector of observations for the dependent variable

$$\mathbf{Y}' = [Y_1 Y_2 \dots Y_n]$$

$\boldsymbol{\beta}$  is the vector of regression parameters

$$\boldsymbol{\beta}' = [\beta_0 \beta_1 \dots \beta_p]$$

$\mathbf{X}$  is the  $n \times (p+1)$  design matrix

$$\mathbf{X} = \begin{bmatrix} 1 & X_{11} & \dots & X_{p1} \\ 1 & X_{12} & \dots & X_{p2} \\ \vdots & \vdots & \ddots & \vdots \\ 1 & X_{1n} & \dots & X_{pn} \end{bmatrix},$$

and  $\boldsymbol{\varepsilon}$  is the vector of random errors.

$$\boldsymbol{\varepsilon}' = [\varepsilon_1 \varepsilon_2 \dots \varepsilon_n]$$

The weighted least squares estimate of  $\boldsymbol{\beta}$  is given by

$$\mathbf{b} = (\mathbf{X}'\mathbf{W}\mathbf{X})^{-1}\mathbf{X}'\mathbf{W}\mathbf{Y}$$

where  $\mathbf{W}$  is the  $n \times n$  diagonal matrix formed from the  $n \times 1$  vector of full sample weights  $\mathbf{w}' = [w_1 w_2 \dots w_n]$  associated with the  $n$  observations in the sample.

If the same weighted least squares estimation procedure is followed using the replicate weights (refer to the next section for a discussion on replicate weights) instead of the full sample weights, then the corresponding replicate estimates of  $\boldsymbol{\beta}$  (denoted by  $\mathbf{b}_{(k)}$ ,  $k = 1, 2, \dots, G$ ) are obtained. An estimate of the variance-covariance matrix of  $\mathbf{b}$  is given by

$$\hat{V}ar(\mathbf{b}) = c \sum_{k=1}^G (\mathbf{b}_{(k)} - \mathbf{b})(\mathbf{b}_{(k)} - \mathbf{b})' \quad (4)$$

where  $G$  is the number of replicates, and  $c$  is the constant that depends on the replication method described in Appendix A of the WesVar Complex Samples Documentation.

For more, including formulae for calculating test statistics, see Appendix C of the WesVar Complex Samples Documentation.

#### 4.1.4 Replication Theory

The basic idea behind replication is to select subsamples repeatedly from the whole sample, calculate the statistic of interest for each subsample, and then use the variability among these subsample or replicate statistics to estimate the variance of the full sample statistic. Different ways of creating subsamples from the full sample result in different replication methods. The subsamples are called replicates and the statistics calculated from these replicates are called replicate estimates. WesVar supports both balanced repeated and jackknife approaches.

The ADSS uses the general stratified jackknife (JKN) method. For a more detailed discussion of replication, its advantages and disadvantages, see Appendix A of the WesVar Complex Samples documentation.

The idea behind replication methods is to calculate the estimate of interest from the full sample, as well as from each subsample or replicate. The variation between the replicate estimates and the full sample estimate is then used to estimate the variance for the full sample. The variance estimator,  $v(\hat{\theta})$ , generally takes the form

$$v(\hat{\theta}) = c \sum_{g=1}^G f_g k_g (\hat{\theta}_{(g)} - \hat{\theta})^2 \quad (5)$$

where

$\theta$  is an arbitrary parameter of interest

$\hat{\theta}$  is the estimate of  $\theta$  based on the full sample

$\hat{\theta}_{(g)}$  is the  $g$ -th replicate estimate of  $\theta$  based on the observations included in the  $g$ -th replicate

$G$  is the total number of replicates formed

$c$  is a constant that depends on the replication method ( $c=1$  for Jkn method)

$v(\hat{\theta})$  is the estimated variance of  $\hat{\theta}$

$k_g$  are the JKN factors

$f_g$  are the finite population correction factors.

The JKN factors are described below and are contained in the file JKN\_FAC2.DAT. For ADSS, the file of JKN factors for Phase II and Phase III are different from JKN factors from Phase I. Contrary to Phase I, the finite population correction (FPC) factors are negligible in Phase II and Phase III. The example that follows shows how the JKN factors are attached. The effect of ignoring these factors is to overstate the variance.

#### 4.1.5 Jackknife n (JKN)

The jackknife n (JKN) method can be used when the number of variance units (referred to as VarUnits in WesVar) in a variance stratum (referred to as VarStrat in WesVar) is greater than or equal to 2. Therefore, the sample design for JKN is more general than for JK2 and Balanced Repeated Replication (BRR), which requires exactly two VarUnits per stratum. The number of replicates,  $G$ , is equal to

$$\sum_{h=1}^L n_h$$

where  $L$  is the number of VarStrat and  $n_h$  is the number of VarUnits in stratum  $h$ . The maximum number of degrees of freedom is  $G-L$ . For ADSS Phase III, 78 replicates were created.

The general computations involved in forming the replicate weights in JKN were as follows. For the first replicate weight, the full sample of observations in the first VarStrat and VarUnit were multiplied by 0 and the weights associated with the other VarUnits in the same VarStrat were adjusted by  $n_h/(n_h - 1)$  to account for reducing the sample. The weights of the observations in other VarStrat were not changed. The remaining  $G-1$  replicates were formed in the same manner by systematically dropping each of the remaining VarUnits and computing the replicate weights as described for the first replicate.

The procedure generated JKN factors ( $k_g$  as shown in equation (5)) that should be applied to the squared deviation of replicate  $g$  from the full sample estimate. The JKN factors are computed as  $k_g = (n_{h'} - 1)/n_{h'}$ , where  $h'$  identifies the stratum that is aligned with replicate  $g$ . Therefore, the factor for the  $g$ -th replicate weight depends on the number of unique values of VarUnit in VarStrat  $g$ .

## 4.2 About the Examples

This document contains examples that are intended to illustrate how to compute weighted estimates and standard errors for ADSS data using WesVar. The examples are from the Phase III the in-treatment methadone client interview and urinalysis data file (P3QUEXI.XPT) and the main study discharge client interview and urinalysis data file (P3QUEXM.XPT). The examples within this document illustrate to the user how to create a WesVar data set from a SAS transport file. Additionally, they show how to create a WesVar workbook to estimate totals and regression parameters and their associated variances.

### 4.2.1 Creating the WesVar File

The first task in creating the WesVar file is to import the SAS File.

**Step 1** From WesVar's main screen, click the New WesVar Data File button or from the menu select **File ► New ► WesVar Data File**.

**Step 2** Select the file that you want to import and click **Open**. (Defaults for the import data file directory and for the WesVar data file directory can be specified in WesVar's Preferences) Choose the data set P3QUEXI.XPT from the **Open** dialogue window. Browse for the folder that the file is in and be sure to change the "Files of type:" to either \*.xpt (transport files) or \*.\* (all files). Any SAS for Windows files (.sd2) must be converted to .ssd or Transport files (.xpt) before being imported. Converting to a .ssd file can be done in SAS using the libname statement: libname libref v604 <'SAS-data-library'>. Converting to a .xpt file can be done using the libname statement: libname libref2 xport <'SAS-data-library'>; along with the PROC COPY procedure (PROC COPY in=libref1 out=libref2; select P3QUEXI.XPT; run;).

Figure 4-1 shows the WesVar Data File screen displays.

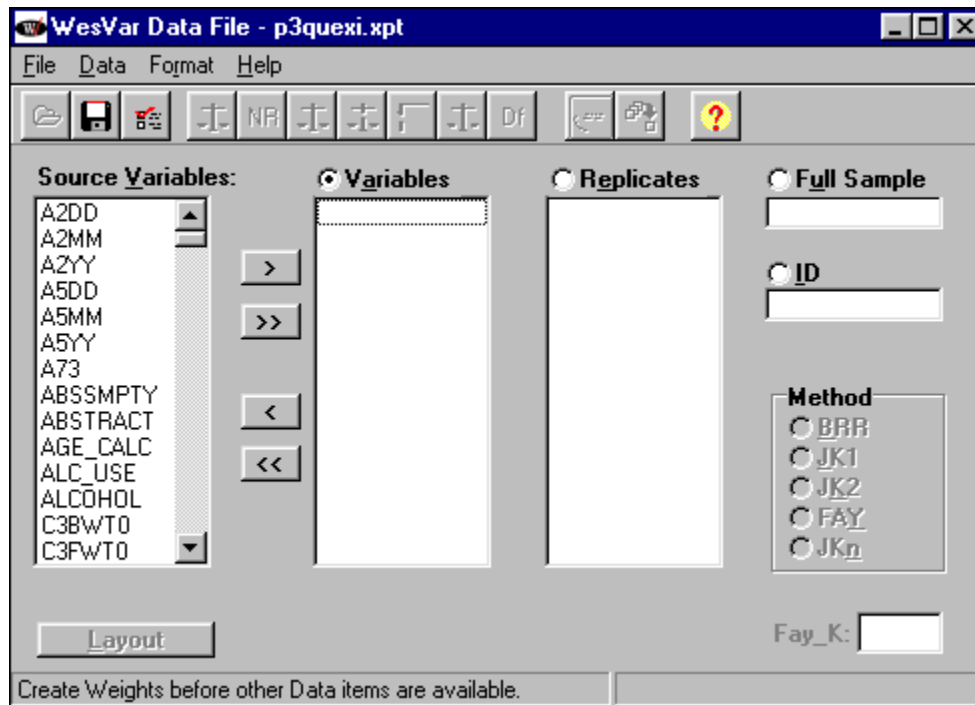

Figure 4-1. WesVar Data File Screen

On this screen you can identify variables, replicate weights, the full sample weight, ID variables, and the replication. An ID variable is one that is used solely to identify the case or record. If you have an ID variable and designate it as such on the WesVar Data File screen, it cannot be used in any Table or Regression request. The ID variables are retained on the WesVar data file and can be extracted later.

The left-hand column lists the source variables that were on the imported file.

- Step 3** Click the appropriate box to identify variables, replicate weights, the full sample weight, or ID variables.
- Step 4** Move variables from the Source Variables list to the appropriate box by double-clicking the variable, using the arrow buttons, or dragging.

As you move the variables, they will disappear from the left-hand column and appear in the appropriate box. It may be easiest to move the ID, Full Sample, and Replicate weights first, and then move the remaining variables simultaneously to the Variables box using the double arrow button.

You do not have to move all of the source variables into the WesVar data file, but any variables left in the Source Variables list cannot be added to the WesVar data file after it is created.

- Step 5** For ADSS data, choose the JKN replication method by clicking on **JKN** in the Method box.
- Step 6** When all variables have been selected and moved, save the imported file as a WesVar file. From the menu select **File ► Save**. The Save As dialog box displays.
- Step 7** To save the file, either click the **Save As** icon on the toolbar or select **File ► Save** from the menu. If you are saving the file for the first time, the Save As dialog box appears. Keep the default file name “P3QUEXI” or type in a new name for the file. WesVar will convert the file from an SAS transport \*.xpt file format to a WesVar \*.var file format.

The WesVar Data File screen in Figure 4-2 shows the variables that were identified and the new file name in the title bar on the screen.

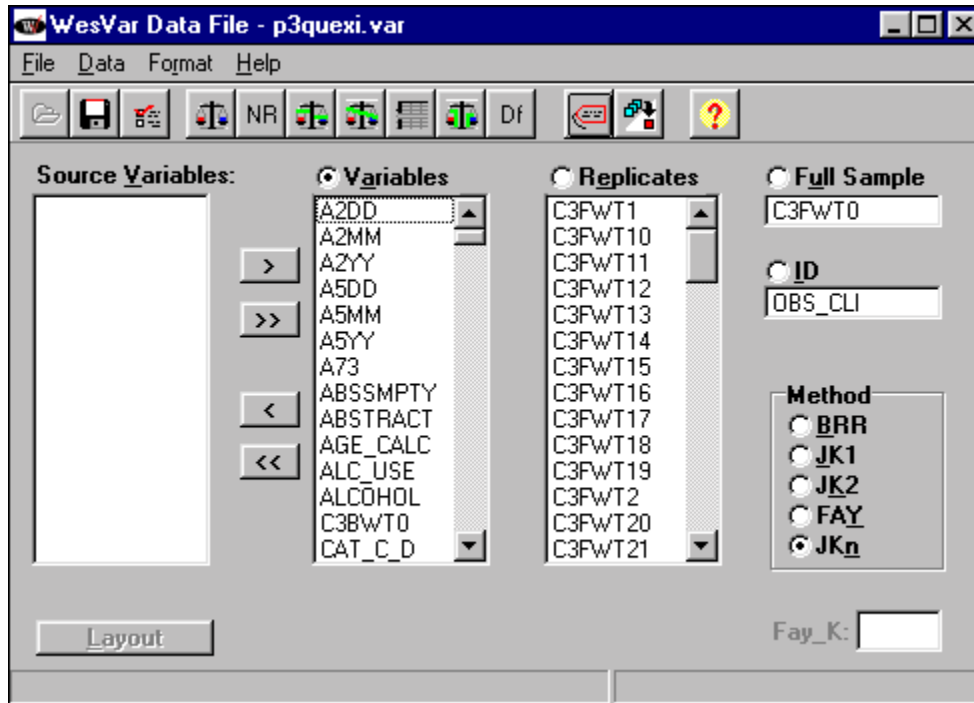

Figure 4-2. WesVar Data File with Replicates

#### 4.2.2 Attach Factors

The Attach Factors feature is an advanced way to attach fpc and JKN factors.

To attach factors:

**Step 1** Open a WesVar data file and from the menu select **Data ► Attach Factors**.

**Step 2** Open the external file that contains the JKN factors. Highlight the column for JKN factors, click **Open**, and select the file JKN\_FAC2.DAT. The first factor in the file is linked to the first replicate, the second factor to the second replicate, etc. There are no fpc factors in Phase III.

After these factors are imported, the screen will look like Figure 4-3.

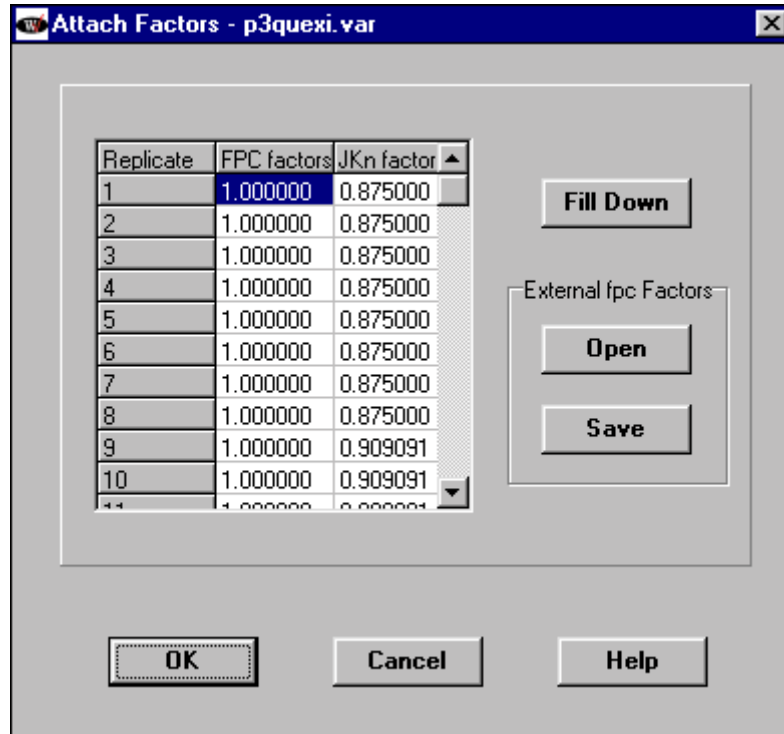

Figure 4-3. Attaching Factors

**Step 3** When all factors have been set, click **OK** then **Save**.

Your WesVar data file has now been created. Exit from the data file screen by double-clicking on the WesVar icon in the top left corner, or by selecting **File ► Close**. To use this .var file, click on **New WesVar Workbook** or select **File ► New ► WesVar Workbook**. Find the .var file you have created and click **Open**.

### 4.2.3 Creating a Table

Click on **Table** on the right side of the screen. Edit the table request by clicking on it and changing the name on the right side of the screen. By clicking on **Generated Statistics** and **Output Control**, you may specify options for this table request. For global changes, type **Ctrl-P**. To create a frequency of a discrete variable, highlight **Table** on the left side of the screen, search for and double-click on the variable of interest under **Source Variables** on the right side. It will then become selected. Click on **Add as New Entry** to incorporate the table request.

Suppose we want to estimate the average age of a client (*AGE\_CALC*), and use *FC53* (During the treatment period, were you / have you been arrested?) as a stratifying variable. This will create separate estimates for average age based on arrest status. Select **Computed Statistics** and *AGE\_CALC* from the list of variables given on the right side of the screen. Select **Block Mean** to incorporate the request of computing the average age. Under **Tables**, choose *FC53* from the list of source variables, being sure to click on the dialog boxes labeled **Percent** under **Sum of Weights**.

In addition to population totals, WesVar allows the option of returning percentages—overall, row, and column. This is done by checking the dialog boxes on the right side of the screen of Figure 4-4.

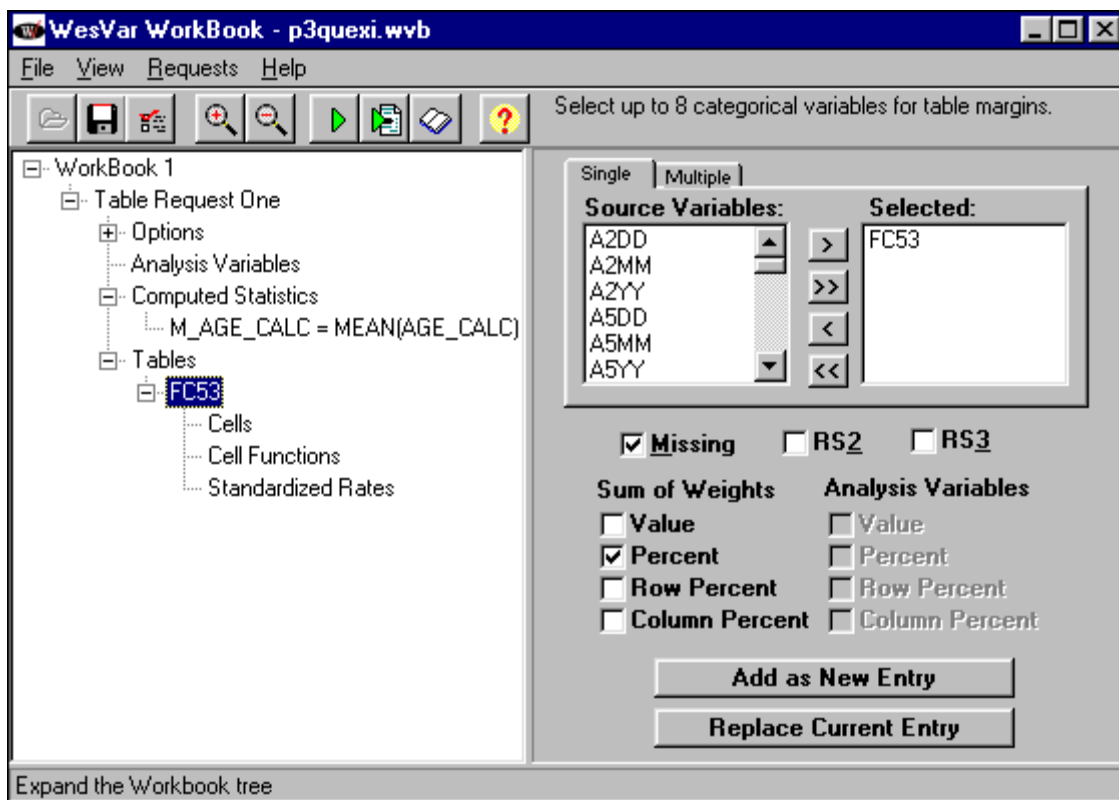

Figure 4-4. Example of Table Request

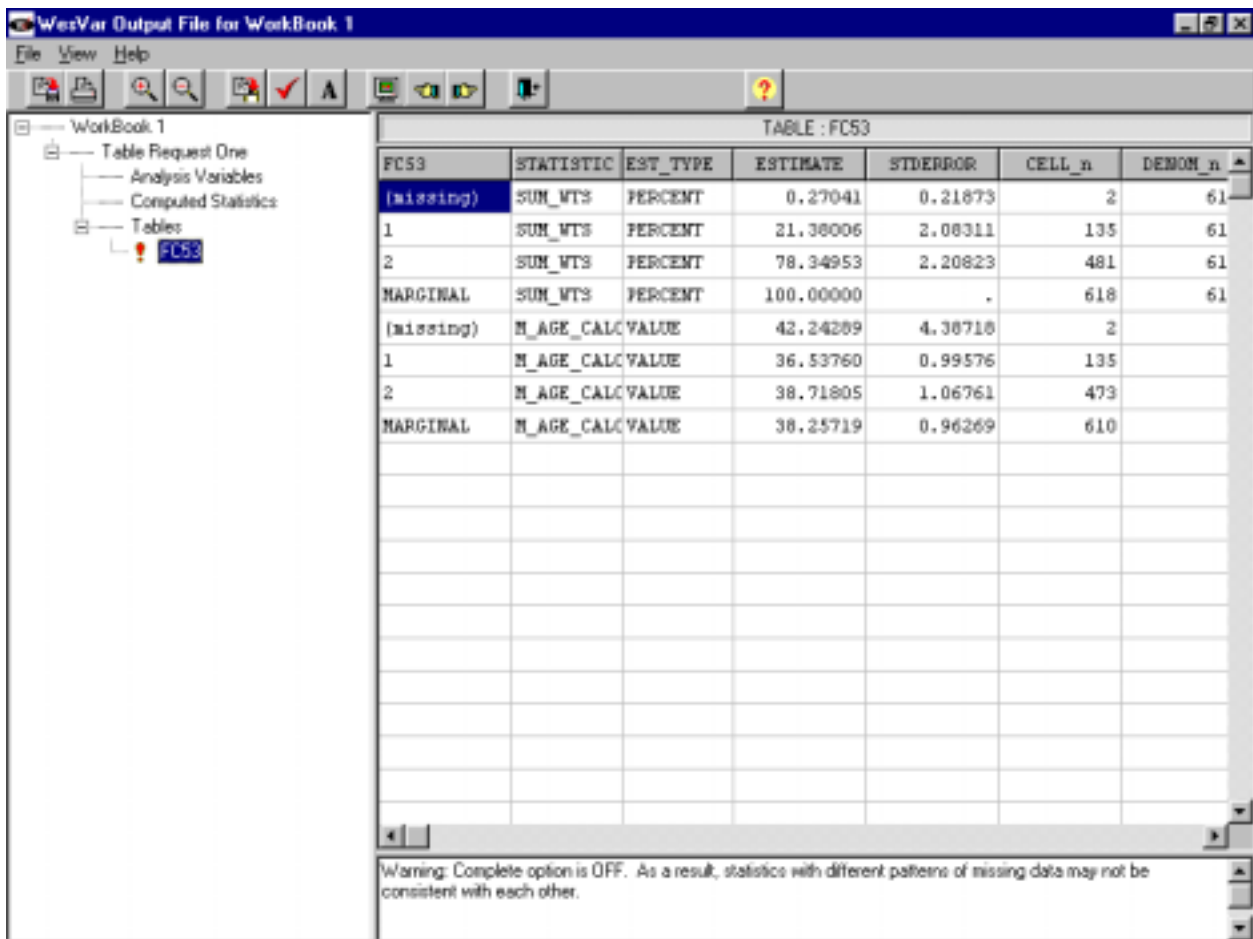

#### 4.2.4 Viewing the Output

When you have finished entering the list of tables, run the request using the green triangle button on the menu bar. When WesVar has completed the table, the button (an open book) for viewing the table turns from gray to white. Click on the button (open book) to view the output. Expand the tree on the left side of the output screen and click on *FC53*. The table appears on the right side of the screen (see Figure 4-5). Errors, if

any, appear as a red exclamation point next to the name of the table, and a message at the bottom right explains the problem.

The output gives estimates of the proportion of people who have or have not been arrested (and includes a category for missing values), and also the average age by each category. Marginal values are also given to estimate the entire population.

Other values, such as standard error and sample size can be reported, but they must be specified under the **Generated Statistics Option** of the Table Request.

FCS3	STATISTIC	EST_TYPE	ESTIMATE	STDERROR	CELL_n	DEMON_n
(missing)	SUM_WTS	PERCENT	0.27041	0.21873	2	61
1	SUM_WTS	PERCENT	21.36006	2.08311	135	61
2	SUM_WTS	PERCENT	78.34953	2.20823	481	61
MARGINAL	SUM_WTS	PERCENT	100.00000	.	618	61
(missing)	H_AGE_CALC VALUE		42.24289	4.38718		2
1	H_AGE_CALC VALUE		36.53760	0.99576		135
2	H_AGE_CALC VALUE		38.71805	1.06761		473
MARGINAL	H_AGE_CALC VALUE		38.25719	0.96269		610

Warning: Complete option is OFF. As a result, statistics with different patterns of missing data may not be consistent with each other.

Figure 4-5. Viewing the Table Output

### 4.2.5 Creating a Regression

Using the file P3QUEXM.XPT, a WesVar data file was created to arrive at the point of discussing the next example. Suppose you want to create a regression to predict how many months the client was using drugs other than alcohol (*FD5*) with the independent variables age at admission (*AGE\_CALC*) and the dichotomous urine result (*U\_ANYDRG*). Select *FD5* from the source variable list (continuous) as the dependent variable by double clicking on the variable. Similarly select *AGE\_CALC* from the source variable list and *U\_ANYDRG[2]* from the class variable list (categorical) as independent variables. After clicking **Add as New Entry**, your screen should look like Figure 4-6.

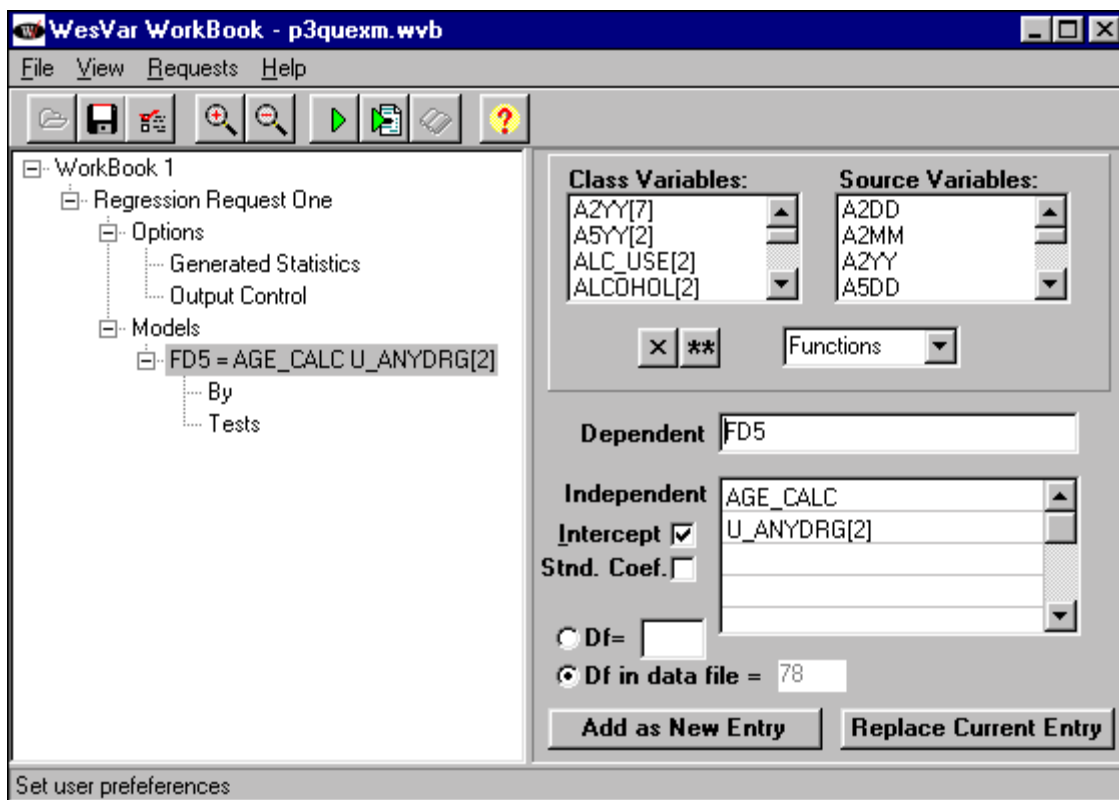

Figure 4-6. Incorporating the Regression Request

Run and view the regression output in the same way as in the table example. Expand the menu on the left side and highlight Estimated Coefficients (see Figure 4-7). The regression output is typical, reporting estimates, standard errors, test statistics, p-values, and an  $R^2$  value.

ESTIMATED FULL SAMPLE REGRESSION COEFFICIENTS				
PARAMETER	ESTIMATE	STANDARD ERROR OF ESTIMATE	TEST FOR H0: PARAMETER=0	PROB> T
INTERCEPT	11.29746	1.92325	5.87415	0.0000
AGE_CALC	-0.12264	0.05122	-2.39451	0.0190
U_ANYDRG.1	-0.98568	0.64376	-1.53112	0.1298
R_SQUARE VALUE =	0.04952			

Figure 4-7. Viewing the Regression Output

#### 4.2.6 Comparing WesVar to SAS

It is often desirable to compare the standard error given by WesVar (taking the complex sample design into account) to a simple random sample standard error. Table 4-1 provides the standard errors of the mean age of clients (*AGE\_CALC*) by arrests during the treatment period (*FC53*). The SAS standard errors were found using PROC MEANS with the options VARDEF=WEIGHT and STD, the CLASS statement *FC53*, and *C3FWT0* as the weight. The resulting standard deviations were then divided by  $\sqrt{n}$  to produce the numbers in Table 4-1.

Table 4-1. Standard errors produced by SAS and WesVar for the levels of *FC53*

<i>FC53</i>	SAS	WesVar
1	0.64951	0.99576
2	0.39135	1.06761
marginal	0.33820	0.96269

The difference between the standard errors from SAS and WesVar shows the effect that the ADSS sampling and weighting procedures have on the variances.

### 4.3 Analysis Issues

The default degrees of freedom for WesVar tabular and regression analysis is the total number of replicates.<sup>8</sup> This may be appropriate for large domains such as ADSS analytic strata, since the number of active replicates at each stratum level is relatively large. However, for small domains, the approximate degrees of freedom need to be specified. The degrees of freedom can be specified in the **Options** panel for tables and the **Models** panel for regression. To approximate the degrees of freedom in an analysis, use the variables for variance strata (*VST\_PSU*) and variance unit (*VUN\_PSU*). For the Phase III clients in the domain of interest, count the number of unique combinations of *VST\_PSU* crossed with *VUN\_PSU* (e.g., number of active replicates) and subtract the number of unique values of *VST\_PSU* (number of variance strata). For instance, for an analysis involving all Phase III clients in the main sample, the number of active replicates is 61 and the number of variance strata is 5, so the approximate degrees of freedom is 56. In general, for any domain of interest in the Phase III analysis of clients, degrees of freedom should be computed.

### 4.4 Alternative Software for Analyzing Survey Data

This section summarizes two alternative software packages, SUDAAN and Stata, that were developed for analyzing data from complex surveys. Both packages can be used with ADSS data.

---

<sup>8</sup> The default degrees of freedom for tabular requests may be modified by the user on the **Tables(2)** tab under **File...Preferences**. The options are Infinite, Number of Replicates, and User Specified.

#### 4.4.1 SUDAAN

The section is intended to help readers who are already somewhat familiar with SUDAAN in their use of SUDAAN when analyzing ADSS Phase III data. SUDAAN requires the selection of a DESIGN option and the identification of variables in a number of required and optional command statements, such as the NEST command. The section describes the possible choices that are appropriate with ADSS data and indicates some of the strengths and weaknesses associated with them.

##### Choice of Design

In SUDAAN, three DESIGN options may seem appropriate for use with ADSS Phase III data, one taking a replication approach and the two others making use of the Taylor's series expansion method. These three options are discussed below.

##### DESIGN = JACKKNIFE

This option does not allow the current replicate weights on the file to be read in. Using DESIGN = JACKKNIFE (replication) is a reasonable option, but it should be used cautiously since the approach of replicating final full sample weights may cause serious overestimates of sampling error. Recent work by Brick, Morganstein, and Barrett (1999) has shown some serious overestimates of variance estimates for totals, and to a lesser extent for means and proportions, for three national surveys using this technique. Results depend on the correlation of the survey items with the weighting variables, levels of nonresponse, and effects of trimming of weights (poststratification or raking to known control totals was not done in Phase III). One can use the NEST command to give levels of the design (stratum and primary sampling unit (PSU)). A description of the use of the NEST command is provided in the paragraph **The Nest Command** in this section. For DESIGN = JACKKNIFE, one can use the ADSS variables *VST\_PSU* and *VUN\_PSU*, which were used as stratum and PSU variables for producing stratified jackknife replicates for use in WesVar.

##### DESIGN = UNEQWOR

Another option is DESIGN=UNEQWOR, which uses Taylor's expansion for estimating variances. This option, however, may not be practical since the computation of joint probabilities under systematic sampling is very complex for analysts to incorporate. The fpc factor can be ignored in Phase II.

##### DESIGN = WR

The most reasonable SUDAAN option to use is DESIGN = WR (Taylor's expansion). The option WR will produce overestimates of variance where the sampling fraction is high in noncertainty strata. However, in Phase II, and thus Phase III, the sampling fractions were low. One can use the NEST statement to give levels of the design (stratum and PSU). Again, the effects of the weighting process will not be fully accounted for using this procedure.

### **The Nest Command**

To analyze ADSS Phase II data, the required NEST command can specify *VST\_PSU* and *VUN\_PSU* as the variables designating stratum and PSU, respectively. For a further explanation of these variables and the methodology used to create them, see Krenzke and Mohadjer (2000). If desired by a user, ADSS variables *PAIR90*, *FIELDPSU*, and *QFSTRAT* can be employed to derive alternative stratum and PSU variables. In interpreting *PAIR90*, it should be noted that a 1<sup>st</sup> character = A identifies certainty geographic regions, a 1<sup>st</sup> character = B identifies noncertainty metro geographic regions, and a 1<sup>st</sup> character = C identifies noncertainty non-metro geographic regions. A user who defines his or her own strata and PSU variables for SUDAAN should also take note that, in addition to the cluster sampling of geographic regions, Phase II facilities were selected from Phase I facilities through stratified PPS sampling with strata identified by the *QFSTRAT* variable.

### **Population and Sample Size Variables**

The population and sample size variables that exist in Phase I and Phase II do not apply in Phase III since the finite population correction factors are negligible, and there are no population control totals that are available for the Phase III target populations.

#### **4.4.2 Stata**

In the Stata software, the Taylor's expansion methods are used to estimate variances. The software offers several *svy* statements to cover several different types of analyses, including means, totals, and ratios. The stratum population sizes are needed if the *fpc* factors are to be incorporated. The function *svyset* sets up the sampling strata and the PSU identifiers. Since raking from Phase II (facility weights) may have an effect on the variances for client-level estimates, and since Stata does not incorporate such an effect into the

variance estimates, results from Stata should be interpreted cautiously. In addition, as in SUDAAN, the variance estimates do not reflect the effects of nonresponse weighting adjustments and weight trimming. Variance estimates are generally higher than those from WesVar.

#### **4.4.3 Comparing WesVar, SUDAAN, and Stata**

Resulting variances are different depending on the software package being used. The magnitude of the differences between the results from the software packages depends on several factors, including type of analysis, impact of systematic sampling, and impact of weighting procedures. It is important for the user to understand how the standard errors were computed. Furthermore, data users are encouraged to consult the software developers of WesVar, SUDAAN, and Stata.

Broene and Rust (1998) prepared a report for the National Center for Education Statistics (NCES) documenting their evaluation of statistical software packages for NCES data sets. At the time of the evaluation, both SUDAAN and Stata used a linearization approach to variance estimation; SUDAAN's latest version includes replication methods. Broene and Rust's paper mentions that SUDAAN is probably the most powerful of the three packages, but may be the most difficult to learn. They conclude that WesVarPC (soon to be WesVar 4.0) was both easy to learn and powerful but lacks some of the model fitting capabilities that SUDAAN has. Furthermore, they mention that Stata is more limited in its survey data analysis capabilities and can be slower to run. Nevertheless, it does enable one to easily plot and examine predicted values and residuals when model-fitting. They mention that all three packages compute standard errors for proportions and for continuous statistics such as means, totals, ratios, and differences in these quantities. For categorical analysis, SUDAAN and WesVar were recommended.

Since the time of the Broene and Rust report, several enhancements were made to each software package. Table 4-2 compares some current features of each package (WesVar 4.0, SUDAAN 7.5, and Stata 6.0). Note that Stata is fully programmable, meaning that, if Stata does not already have a specific function, a program may be created to satisfy individual needs.

Table 4-2. Analysis capabilities for WesVar, SUDAAN, and Stata

	WesVar 4.0	SUDAAN 7.5	Stata 6.0
Standard errors and design effects for means, totals, proportions, ratios	X	X	X

## EVER HAD A DRINK OF ALCOHOL

Now I would like to ask about your use of alcoholic beverages. By alcoholic beverages I mean beer, malt liquors, wine, wine coolers and hard liquor, such as vodka and mixed drinks.

Have you ever had a drink of alcohol? By a drink, I mean either a can of beer, a glass of wine or a wine cooler, a shot of hard liquor, or a single mixed drink.

If No -> Go To B14

PERSON INCOM 12MO.BEFOR ENTER TX MORE OR LESS THAN \$20,000

The next two questions are about your total personal income from all sources during the 12 months before you entered treatment. Include money from your jobs, social security, retirement income, unemployment payments, public assistance, and so forth. Also include income from interest, dividends, net income from business, farm, rent, and any other money income you received.

Income data are important in analyzing the health information we collect. For example, the information helps us to learn whether persons in one income group use certain types of health care or treatment services or have conditions more or less often than those in another group. Was your total personal income during the 12-month period before you entered treatment more or less than \$20,000?

If 1 then go to B44a. If 2 then go to B44b.
